

Request handling

Request handling in Flask is the process by which the Flask application receives an HTTP request from the client, processes it, and sends an appropriate response back to the client.

What is Flask?

Flask is a lightweight and open-source web framework developed using Python. It is used to create web applications quickly and efficiently.

Request Handling Process in Flask

1.Client Sends Request

- 1.The user enters a URL in the browser.
- 2.The browser sends an HTTP request to the Flask server.

2.URL Routing

Flask checks the requested URL.

The URL is matched with a route defined using the `@app.route()` decorator.

3. View Function Execution

Flask executes the corresponding view function.

The function processes the request and performs the required operations.

4.Database Interaction (Optional)

If necessary, the application retrieves or stores data in the database.

5. Response Generation

Flask generates a response such as an HTML page, JSON data, or plain text.

6. Response Sent to Client

The browser receives and displays the response to the user.

Explanation of the Program

- Flask(__name__) creates the Flask application.
- @app.route('/') maps the URL / to the home() function.
- When the user visits the home page, the home() function executes.
- The function returns the message "**Welcome to Flask**" to the browser.

```
from flask import Flask

app = Flask(__name__)

@app.route('/')
def home():
    return "Welcome to Flask"

if __name__ == '__main__':
    app.run(debug=True)
```

Advantages of Flask Request Handling

- Simple and easy to understand.
- Supports multiple HTTP methods.
- Flexible routing mechanism.
- Suitable for small and medium-sized web applications.
